Introduction:

In adult macaque monkeys, after lesion of the cervical cord, neutralization of the neurite outgrowth inhibitor protein Nogo-A leads to significant sprouting of corticospinal axons and to behavioral improvements. The data reflecting enhanced functional recovery were based on a global quantitative evaluation of manual dexterity as well as on a couple of semi-quantitative test (Freund et al. 2006). The present investigation aims at refining the analysis of the standard behavioral assessment of manual dexterity ("modified Brinkman board" task) with the goal to better assess the impact of a lesion at cervical level as well as the time course and extent of recovery, comparing control antibody and anti-Nogo-A antibody treated monkeys.

Materials and Methods:

- ~ 13 young (3-5 years) adult macaque monkeys weighing from 3.5-5.5 kg were subjected to an unilateral section of the cervical cord (C7/C8 border)
- ~ Quantitative assessment of manual dexterity pre- and post-lesion: **Modified Brinkman board** task, the time required to manipulate and extract the first pellet aimed for by the animal was analyzed and the total number of pellets retrieved within the first 30s from vertically and horizontally slots was counted.
- ~ Lesion extent: Total surface of the sectioned hemi-cord against the entire hemi-cord.
- ~ 7 monkeys were treated with an anti-Nogo-A specific antibody, whereas a control antibody was intrathecally infused in the other six monkeys.
- ~ A new statistical test was introduced to assess the overlap/segregation between two groups of data (Figures 2E,F; 4C,D), taking into account two parameters, namely the extent of the lesion and the percent of functional recovery. We use Fisher's linear discriminant function providing maximal separation between the two groups.

Conclusion:

We conclude, based on a newly introduced readout of the behavioural assessment of the manual dexterity (contact time in the "modified Brinkman board" task) and a more appropriate statistical analysis, that anti-Nogo-A antibody treatment promotes significant improvement of functional recovery from cervical cord hemi-section in adult macaque monkeys. Moreover, no negative side effects, such as allodynia, were observed during the entire administration of the anti-Nogo-A antibody treatment.
